DEPARTMENT OF THE ARMY  
HEADQUARTERS US ARMY AVIATION MATERIEL LABORATORIES  
FORT EUSTIS, VIRGINIA 23604

This report has been reviewed by the U. S. Army Aviation Materiel Laboratories and is considered to be technically sound. The data presented were obtained from oscillograph recorders installed on three U. S. Army AH-1G helicopters performing operational missions in Southeast Asia. These data indicate the missions flown and the accelerations associated with the combatant deployment of this aircraft. The report is published for the exchange of information and the stimulation of ideas.

## ABSTRACT

From a structural flight loads program on three AH-1G helicopters, 408.2 hours of valid multichannel flight data were recorded as the helicopters operated from bases in Southeast Asia. Data were processed and analyzed according to four distinct flight phases, termed mission segments: (1) takeoff and ascent; (2) maneuver; (3) descent, flare, and landing; and (4) steady state. Data are presented in the form of time and occurrence tables, histograms, and exceedance curves. These data indicate the time spent in the mission segments and parameter ranges; the number of peak parameter values occurring in the ranges of the given parameter, during each of the mission segments, and in the ranges of one or more related parameters; and the time to reach or exceed given maneuver and gust normal load factors. The data are presented in two samples of 201.7 hours and 206.5 hours. These samples, identified as Sample I and Sample II respectively, were obtained consecutively. Sample I was recorded between August 1968 and April 1969, and Sample II was recorded between April 1969 and November 1969. This separate presentation is made to permit an evaluation of the validity of the 200-hour sample as an adequate data base. The differences between the two samples were minor, and the two samples were observed to be similar in their distributions of flight data.

## FOREWORD

Technology Incorporated, Dayton, Ohio, prepared this report to cover its efforts on a flight loads data program to collect, process, and analyze a 400-hour sample of valid flight data obtained from three AH-1G helicopters operating in Southeast Asia. This program was sponsored by the U. S. Army Aviation Materiel Laboratories, Fort Eustis, Virginia, under Contract DAAJ02-68-C-0076, Task IF162204A14607. The project monitor for the Army was Mr. William T. Alexander.

The prime Technology Incorporated personnel engaged in this program were as follows: Mr. Henry C. Pender, project engineer, who directed the installation and operation of the data recording systems; Messrs. John F. Nash and Ronald I. Rockafellow, who directed the data processing; Mr. William E. Morrin, who directed the computer programming for the data processing; and Mr. F. Joseph Giessler, who assisted in the data presentation and compilation.

## INTRODUCTION

For the continued Army study of helicopter operations, a multichannel flight loads program was conducted on five AH-1G helicopters flying combat missions in the Vietnam theater from July 1968 to January 1970. During this period, 436 hours of valid in-flight data were recorded for each of ten time-related parameters. The chosen parameters were selected to reflect the structural loads along the three major axes in the light of various helicopter variables. As reported in References 1 through 5, similar multichannel data were previously collected in five programs on the UH-1B, CH-54A, and CH-47A helicopters. Of these programs, three—one for each model—were conducted under test and training conditions, and two—each for the CH-47A model—were conducted under combat conditions.

The AH-1G "Huey Cobra" helicopter is a highly maneuverable, high-speed gun ship. Deployed as a ground-support weapons platform, the AH-1G has a controllable nose turret and two external store pylons. The nose turret contains a 7.67-mm minigun and a 40-mm grenade launcher, and each of the pylons carries such armament as the XM-159C, XM-157, XM-18, and XM-159. The crew consists of a pilot and a copilot/gunner. To illustrate the general configuration of the AH-1G, Figure 1 presents a photo and a multiview drawing of this helicopter model. In addition, this figure contains basic data identifying some of the aircraft operational characteristics and limitations.

The oscillograph type of recording system was employed to measure the following ten in-flight variables: airspeed; altitude; normal, lateral, and longitudinal acceleration at the aircraft's center of gravity; outside air temperature; rotor rpm; collective pitch stick position; longitudinal cyclic pitch stick position; and engine torque—all related in time. Field personnel logged additional information to permit the computer processing of the in-flight recordings. Such supplementary data consisted of time, fuel, and armament at takeoff and landing; base pressure and temperature at takeoff; mission type; and aircraft configuration. The data processing derived additional parameters: specifically, the instantaneous weight, the rotor tip speed ratio, and the ratio of the thrust coefficient to the rotor solidity. In addition, for the more meaningful interpretation of all parameters, the data for each flight were divided into four phases, called mission segments: (1) takeoff and ascent; (2) maneuver; (3) descent, flare, and landing; and (4) steady state.

All previous helicopter flight loads programs, such as those reported in References 1 through 5, were designed to collect 200 hours of valid in-flight data. The AH-1G program, however, sought the collection of 400

### Summary of AH-1G Characteristics and Limitations

Characteristics:

disc area	1520 sq ft
rotor solidity	0.0652
airfoil section	9-1/3T special symmetrical
wing area	28.2 sq ft
engine	Lycoming T53-L-13
des. max. gross wt.	9500 lb
empty weight	5382 lb

Limitations

normal rate power	1250 hp
takeoff power	1400 hp
usable power (transmission limit)	1100 hp
usable power/des. max. gross wt.	0.116
max. airspeed (1100 hp)	158 kt
max. allowable airspeed	190 kt

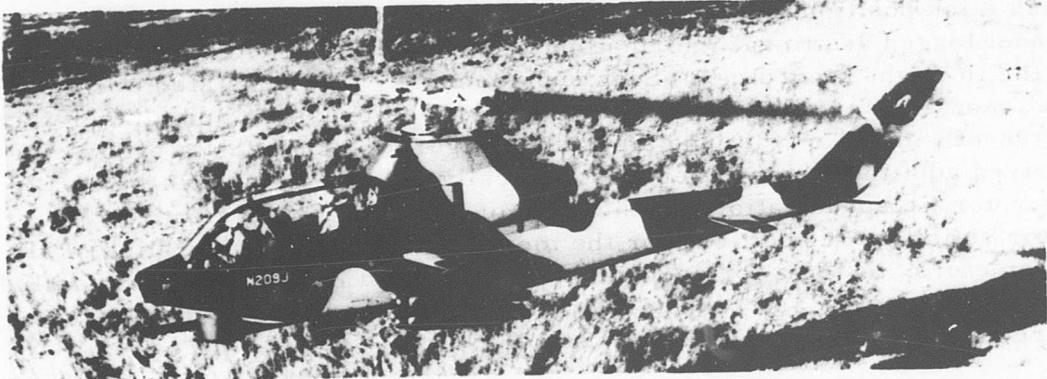

Figure 1. Photo and Multiview Drawing of AH-1G Helicopter.

hours to be chronologically separated into two data sets of 200 hours each. The two data sets were planned to make comparisons that would test the validity of 200 hours as an adequate data sample. Accordingly, the valid 200 hours collected between August 1968 and April 1969 comprised the first set, and the valid 206 hours recorded from April 1969 to November 1969 made up the second set.

The objective of the AH-1G program, therefore, was twofold: (1) to present comprehensive flight loads data on the current operation of this helicopter model in the combat environment of Vietnam, and (2) to test the validity of the 200 hours as an adequate data sample.

This report describes the aircraft instrumentation and the recording system, details the data collection, defines the recorded and derived parameters, outlines the data processing and quality control, explains the data computations, and finally presents and analyzes the processed data. Both sets of data were treated separately, and the results are presented as histograms of the percentages of time within various parameter ranges; as "exceedance" curves, that is, curves of the number of flight hours required for a parameter to reach or exceed given levels; as tables of time distributed among the coincident ranges of two or more parameters; and as tables of peak frequencies in the coincident ranges of the peaking parameter and other variables.

## AIRCRAFT INSTRUMENTATION

At the Southeast Asia facility of the Army's 334th Aviation Company, an oscillographic recording system was initially installed in each of three AH-1G helicopters, identified by serial Nos. 67-15546, 67-15538, and 67-15562. The subsequent loss of two of these aircraft in combat necessitated the installation of similar recording systems in two additional AH-1G's (serial Nos. 67-15694 and 68-15612).

After each selected helicopter was equipped with the Class A provisions to accommodate its recording system, the components were installed as follows: A Century Model 409B oscillographic recorder to measure all ten in-flight parameters was positioned on a shelf behind the pilot's seat, and a Technology Incorporated Model 49776 bridge control unit to regulate the voltage signals from the various transducers was mounted on top of the recorder.

To derive airspeed, a Satham Model P196TC-1-350 ( $\pm 0.5$  psid) pressure transducer was employed to measure the dynamic pressure. To derive pressure altitude, a Satham Model P96-15-350 (0 to 15 psia) pressure transducer was employed to measure the absolute atmospheric pressure. Both transducers were mounted below the pilot's instrument panel and connected to the aircraft's pitot-static system.

For the three linear acceleration measurements, two Kistler Model 303B servo accelerometers were employed to sense the lateral and the longitudinal accelerations; a Satham Model C-3-350 accelerometer was employed to sense the vertical acceleration. All accelerometers were mounted beneath the transmission assembly as close as possible to the helicopter's center of gravity.

A frequency-to-voltage converter and associated circuitry were incorporated in the recording system to measure the rotor rpm by sensing the frequency of the rotor tachometer generator. The output signal from the generator was acquired from a terminal board behind the pilot's instrument panel.

A Minco Model S6B resistance thermal ribbon, used to measure the outside air temperature, was installed near Fuselage Station 200.

Two Lockheed Electronics Co. Model WR-8-15B position transducers were employed to sense the stick positions of the collective pitch and the longitudinal cyclic pitch controls. Both transducers were installed

beneath the transmission assembly and connected to each of the stick control tubes.

To measure the engine torque pressure, a Rahm Model PT 71-2 (0 to 100 psid) pressure transducer was installed in the engine compartment and then connected in parallel with the helicopter's torque pressure transmitter.

The block diagram in Figure 2 illustrates the functional integration of the components comprising the recording system.

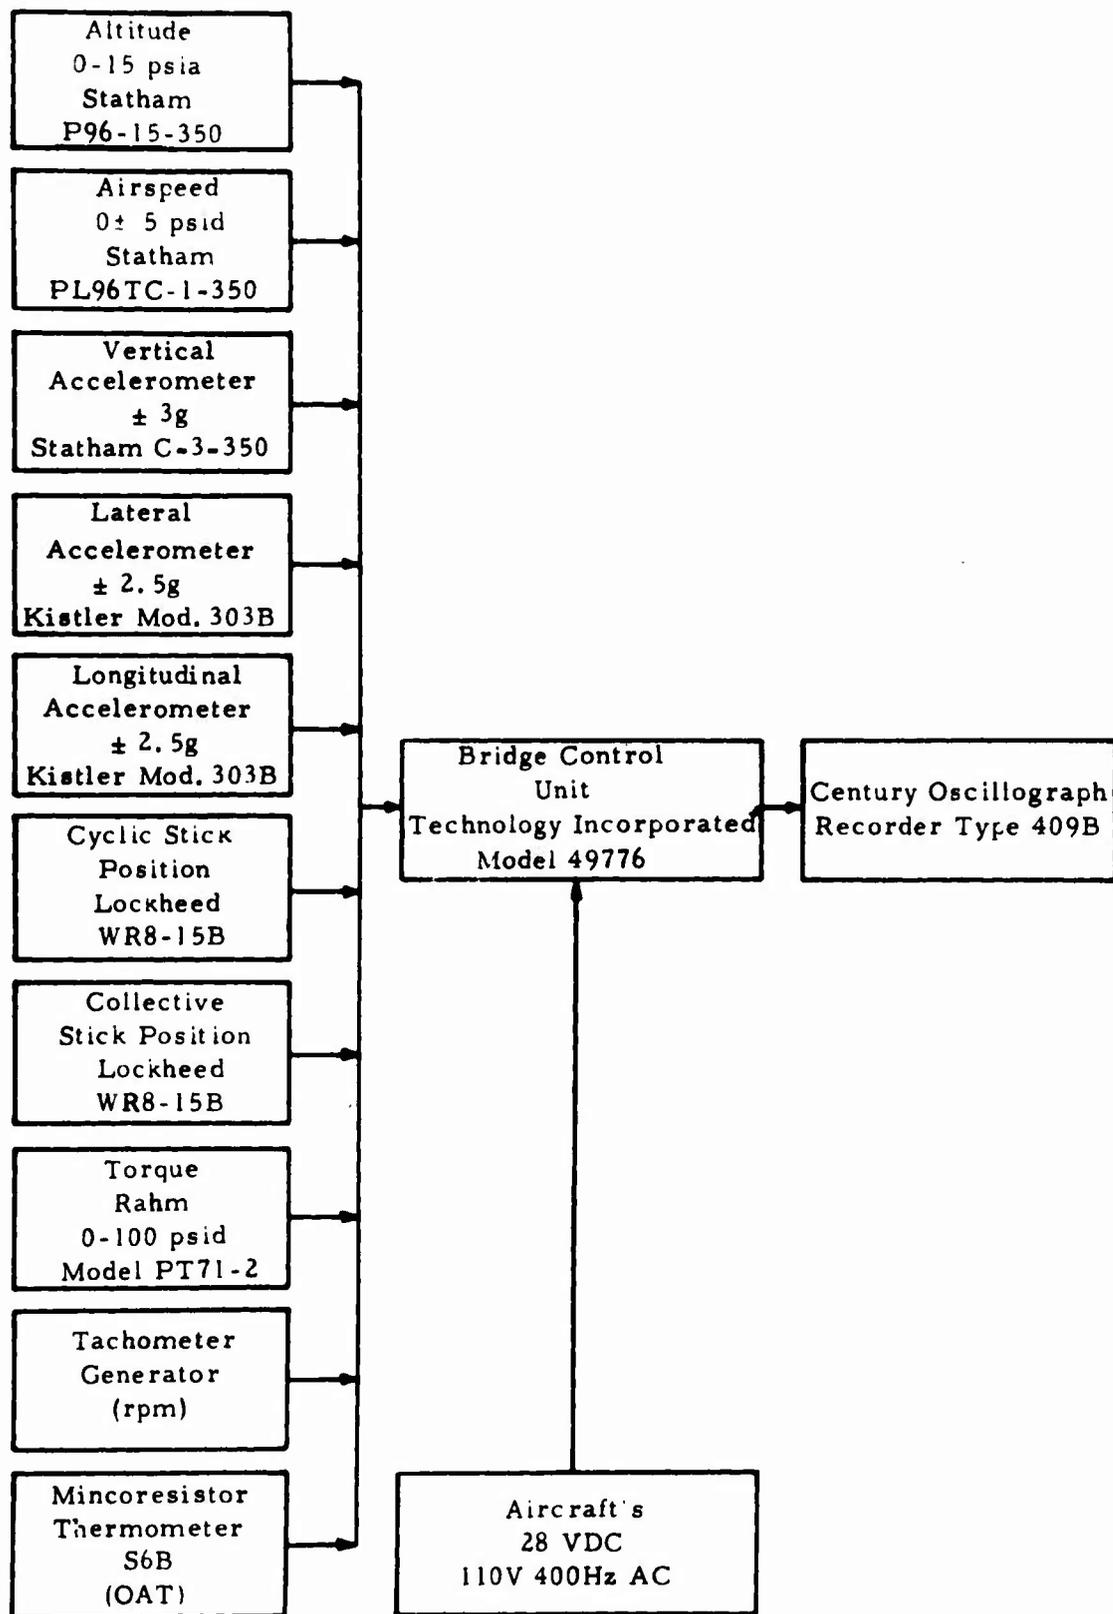

Figure 2. Block Diagram of AH-1G Instrumentation System.

## OSCILLOGRAPHIC RECORDER

The Century Model 409B recorder with fourteen data channels, each capable of recording a dynamic or a static parameter on a 3-5/8-inch-wide photo-sensitive paper, was employed in this program because of its inherent design to withstand severe shock and vibration and extreme environmental conditions. In this program, ten channels were used to record the in-flight variables. Of the remaining four channels, one was used to monitor the voltage supply, another was employed to delineate a time pattern reflecting a 1-minute cycling, and the last two were used to trace constant lines for measurement references.

In this program the recording system operated from two types of power supplied by the helicopter: 110 v, 400 Hz ac, which after rectification was used in the special frequency-to-voltage circuit to measure the rotor rpm, and 28 vdc, which was used for all other operations. The recording system was normally operative when the helicopter power was on. However, the pilot could stop the recorder when extensive ground operation was anticipated and then restart it upon the resumption of flight.

## DATA COLLECTION

During the data collection period from July 1968 to January 1970, 1206 hours of in-flight data were recorded. Of these hours, 436 were valid; and 408 in two sets of 202 and 206 hours were processed for the data presentation in this report. Some of the discrepancies causing the 770 hours of invalid data were erratic trace deflections, no trace deflection, insufficient trace deflection, malfunction of the oscillogram drive motor, bad galvanometer, and no supplemental flight data. When developing the oscillogram and observing such discrepancies, the field technician was aware of the cause of most of the malfunctions and took remedial action as soon as possible. Much of the flying time could not be recorded because of extended helicopter operations away from the home base which precluded changing the oscillograph magazines. In addition, severe helicopter operations at times resulted in damage to some of the accelerometers and outside-air-temperature sensors. Occasionally, malfunctions in the helicopter system prevented the recording of the parameters intended to monitor the helicopter's mechanical operation, notably rotor rpm and engine torque.

After each recorded flight, the field technician, aided by the pilot, filled out a special form to log the supplemental data needed to process the oscillogram data. Such additional information included the flight date; helicopter configuration; mission type; airspeed and rotor rpm at check points; takeoff elevation, atmospheric pressure, and temperature; and at both takeoff and landing, the base, time, fuel, and armament weight. In addition, the field technician logged the serial number for each transducer to permit correlating the calibration data with the recorded data during the final data processing.

## DATA DEFINITIONS

### RECORDED PARAMETERS

The ten in-flight parameters recorded on the oscillograms against a time base consisted of (1) altitude, (2) airspeed, (3) outside air temperature, (4) vertical acceleration, (5) lateral acceleration, (6) longitudinal acceleration, (7) rotor rpm, (8) engine torque pressure, (9) longitudinal cyclic pitch control stick position, and (10) collective pitch control stick position. For each of these parameters, Table I lists the ranges selected to study the parameter relationships most practically and significantly.

With the assumption of a standard atmosphere prevailing during the data recording, the altitude and airspeed trace measurements, proportional to the static pressure and the pitot-static pressure differential, respectively, were converted from pressure units to the conventional pressure altitude and indicated airspeed units. The outside air temperature was then used to convert pressure altitude to density altitude, the derived form of the altitude expressed in the final data. Of the remaining parameters, acceleration is represented as a load factor, engine torque as a torque pressure, and the control stick positions as percentages of full deflection with both the full-forward position of the cyclic pitch stick and the full-down position of the collective pitch stick being zero percent.

### COMPUTED PARAMETERS

From the fuel and armament at takeoff and landing, as logged on the supplemental data sheets, the gross weight was computed for the start and end of each flight. A constant rate of fuel consumption was assumed to obtain an average weight-loss rate that was used to compute the instantaneous gross weight. Weight losses because of armament drops were introduced at the times noted on the supplemental data sheets.

For each data reading point, two derived parameters were added to the data bank: (1) the rotor tip speed ratio, and (2) the ratio of the thrust coefficient to the rotor solidity.

The rotor tip speed ratio,  $\mu$ , was computed by

$$\mu = \frac{V}{\Omega R}$$

where  $V$  = airspeed, ft/sec  
 $\Omega$  = rotor angular velocity, rad/sec  
 $R$  = rotor radius, ft

7 ≥ 60 to < 70
8 ≥ 70

And the ratio of thrust coefficient to the rotor solidity, that is,  $C_T/\sigma$ , was computed by

$$C_T/\sigma = \frac{W}{\rho^2 (OR)^2 \sigma}$$

where  $C_T$  = thrust coefficient  
 $W$  = gross weight, lb (instantaneous)  
 $\rho$  = air density at altitude, slugs/ft<sup>3</sup>  
 $\sigma$  = rotor solidity

#### MISSION SEGMENTS

For the more meaningful analysis of the helicopter performance and loads, the data for each flight were separated into four mission segments: (1) takeoff and ascent; (2) maneuver; (3) descent, flare, and landing; and (4) steady state. The first three segments are the transient, or unsteady, regimes of flight and were distinguished from the steady-state segment by the variation in the stick position, airspeed, and altitude traces. The segments were identified and defined as follows: Mission Segment 1 (takeoff and ascent) included both the takeoff and climb to the initial cruise altitude and all other unsteady ascents to other altitudes. Mission Segment 2 (maneuver) included all weapons passes and those altitude changes not appearing in Segments 1 or 3. Mission Segment 3 (descent, flare, and landing) included the unsteady part of flare and landing and all other unsteady descents. Mission Segment 4 (steady state) included cruise, hover, steady ascent (after the initial climb), and steady descent. Flare and landing initiated from hover was included in Mission Segment 4. Such steady-state parts were evidenced by minimal fluctuation of the stick position traces about mean values and the constancy or smooth change of the airspeed and altitude traces.

## DATA PROCESSING

### DATA EDITING

Each oscillogram is examined by the data processing editors for evidence of any instrumentation anomaly such as a missing trace, improper sensitivity, etc. Any record discovered as faulty is classified as malfunction data and is not processed. The editors then time all acceptable records and identify the bounds for the four mission segments in each flight.

After demarcating the flights into mission segments, the editors mark the traces as follows to govern the data reading. The normal acceleration trace was marked wherever a peak met the following two conditions: (1) the peak fell outside prescribed threshold levels ( $\pm 0.2g$  about the 1.0g mean), and (2) the peak had a rise and fall (or fall and rise) that were each 50 percent of the peak value or 0.2g, whichever was greater. Although the prescribed thresholds were 0.8 and 1.2g, the editors used levels of 0.84 and 1.16g to ensure the inclusion of all valid peaks. However, any of the peaks read within the fixed threshold levels of 0.8 and 1.2g were eliminated during the computer processing. In addition, the editors identified each selected peak as being maneuver- or gust-induced. To determine whether a peak was induced by a maneuver or a gust, the editors noted the behavior of the stick position traces. Whenever the peak was the result of maneuvering, one or both of the stick traces would always deflect just before and in the same sense as the peak. Ascertaining that a peak was gust induced was difficult because of the very high activity of the control sticks. Ascertaining the gust-induced peaks required either that both stick position traces be steady or that any movement of these traces just before the peak be in the sense opposite that of the peak.

The editors marked primary peaks on the lateral and longitudinal acceleration traces wherever they deflected outside the prescribed threshold of  $\pm 0.1g$ . These peaks were not identified as being maneuver- or gust-induced. As before, to ensure inclusion of all valid peaks, the editors used levels of  $\pm 0.097g$  in lieu of the  $\pm 0.1g$ . Again, however, any peaks read within the prescribed threshold of  $\pm 0.1g$  were eliminated during the computer processing.

In treating the two stick position traces, the editors marked those peaks whose rise or fall was 10 percent of the full stick travel and at least 10 percent from the normal value. Each normal value depended on the mission segment. For the steady-state mission segment, the normal values were the steady values of the stick positions just before and after the peak. For the three transient mission segments (where no "steady"

stick positions prevailed), an arbitrary set of normal values was chosen to approximate the stick positions during hover. The selected values are listed by aircraft serial number in Table II.

TABLE II. CONTROL STICK NORMAL VALUES USED DURING TRANSIENT MISSION SEGMENTS

Aircraft Serial No.	Longitudinal Cyclic Normal (%)	Collective Normal (%)
67-15562	59.5	41.3
67-15538	58.4	43.5
67-15694	54.6	36.6

In each of the three transient mission segments, all traces except those for the stick positions were marked when the acceleration or stick position traces peaked. During all mission segments, however, all traces except that for acceleration were marked at critical points to permit an adequate representation of the parameters. At the peaks of normal acceleration,  $n_z$ , the corresponding values of longitudinal acceleration,  $n_x$ , and lateral acceleration,  $n_y$ , were read. At the peaks of  $n_x$  and  $n_y$ , the corresponding values of  $n_z$  and cyclic stick position were read.

The peak values of the three linear accelerations were measured from normal positions of the respective traces. For both the vertical acceleration,  $n_z$ , and the lateral acceleration,  $n_y$ , the normal position was defined when the helicopter was at rest. For the longitudinal acceleration,  $n_x$ , the normal position was defined when the helicopter cruised at a 90-knot airspeed. The positive sense of the longitudinal load factor,  $n_x$ , is acceleration forward, and the positive sense of the lateral load factor,  $n_y$ , is acceleration to the right.

#### DATA READING AND QUALITY CONTROL

All data points selected during the editing were measured on semiautomatic oscillogram readers which transcribed the measurements directly to punched cards. When all data were extracted from a flight, a print-out of the cards was given to the Quality Control Section for preliminary data checking. Using standard quality control techniques, this section manually remeasured random points comprising an adequate sample and compared the measurements with those produced by the semiautomatic readers. The differences obtained between the two sets of readings were

used to establish the mean and standard deviations as a control of the desired reading accuracy. The flights whose measurements did not meet the accuracy standard so established were reread by the semiautomatic readers. In addition to obtaining accurate values, this procedure ensured a uniform interpretation and measurement of the traces.

When all data had been processed, the mean and standard deviations were calculated for the entire data sample. Assuming a normal distribution of reading errors, 99.7 percent of the readings should be within three standard deviations of the true values. Based on average calibration values, Table III shows the three standard deviation for each parameter.

TABLE III. DATA READING VARIATIONS BY PARAMETER

<u>Parameter</u>	<u>3<math>\sigma</math> Variation</u>
Altitude	$\pm 224$ ft (at 1000 ft)
Airspeed	$\pm 2.2$ kt (at 120 kt)
$n_x$	$\pm 0.032g$
$n_y$	$\pm 0.032g$
$n_z$	$\pm 0.038g$
OAT	$\pm 0.84^\circ$ F
Rotor rpm	$\pm 4.4$ rpm
Engine Torque	$\pm 1.9$ psi
Collective Pitch	$\pm 3.0\%$
Cyclic Pitch	$\pm 3.6\%$

#### DATA COMPUTATIONS

The load factor,  $n_z$ , for each normal acceleration peak was measured directly from the oscillogram trace. However, to present load factors for positive and negative peaks conveniently, an incremental normal load factor,  $\Delta n_z$ , was derived from each  $n_z$  value by using the relationship

$$\Delta n_z = n_z - 1.0$$

The following equation (see Reference 6) was used to compute density altitude, since this parameter is normally used in describing helicopter performance:

$$h_d = 145,300 \left[ 1 - \left( \frac{518.4 P_a}{29.92 (OAT + 460)} \right)^{0.235} \right]$$

stick positions prevailed), an arbitrary set of normal values was chosen to approximate the stick positions during hover. The selected values are listed by aircraft serial number in Table II.

TABLE II. CONTROL STICK NORMAL VALUES USED DURING TRANSIENT MISSION SEGMENTS

<u>Aircraft Serial No.</u>	<u>Longitudinal Cyclic Normal (%)</u>	<u>Collective Normal (%)</u>
67-15562	59.5	41.3
67-15538	58.4	43.5
67-15694	54.6	36.6

In each of the three transient mission segments, all traces except those for the stick positions were marked when the acceleration or stick position traces peaked. During all mission segments, however, all traces except that for acceleration were marked at critical points to permit an adequate representation of the parameters. At the peaks of normal acceleration,  $n_z$ , the corresponding values of longitudinal acceleration,  $n_x$ , and lateral acceleration,  $n_y$ , were read. At the peaks of  $n_x$  and  $n_y$ , the corresponding values of  $n_z$  and cyclic stick position were read.

The peak values of the three linear accelerations were measured from normal positions of the respective traces. For both the vertical acceleration,  $n_z$ , and the lateral acceleration,  $n_y$ , the normal position was defined when the helicopter was at rest. For the longitudinal acceleration,  $n_x$ , the normal position was defined when the helicopter cruised at a 90-knot airspeed. The positive sense of the longitudinal load factor,  $n_x$ , is acceleration forward, and the positive sense of the lateral load factor,  $n_y$ , is acceleration to the right.

#### DATA READING AND QUALITY CONTROL

All data points selected during the editing were measured on semiautomatic oscillogram readers which transcribed the measurements directly to punched cards. When all data were extracted from a flight, a print-out of the cards was given to the Quality Control Section for preliminary data checking. Using standard quality control techniques, this section manually remeasured random points comprising an adequate sample and compared the measurements with those produced by the semiautomatic readers. The differences obtained between the two sets of readings were

used to establish the mean and standard deviations as a control of the desired reading accuracy. The flights whose measurements did not meet the accuracy standard so established were reread by the semiautomatic readers. In addition to obtaining accurate values, this procedure ensured a uniform interpretation and measurement of the traces.

When all data had been processed, the mean and standard deviations were calculated for the entire data sample. Assuming a normal distribution of reading errors, 99.7 percent of the readings should be within three standard deviations of the true values. Based on average calibration values, Table III shows the three standard deviation for each parameter.

TABLE III. DATA READING VARIATIONS BY PARAMETER

<u>Parameter</u>	<u>3<math>\sigma</math> Variation</u>
Altitude	$\pm 224$ ft (at 1000 ft)
Airspeed	$\pm 2.2$ kt (at 120 kt)
$n_x$	$\pm 0.032g$
$n_y$	$\pm 0.032g$
$n_z$	$\pm 0.038g$
OAT	$\pm 0.84^\circ$ F
Rotor rpm	$\pm 4.4$ rpm
Engine Torque	$\pm 1.9$ psi
Collective Pitch	$\pm 3.0\%$
Cyclic Pitch	$\pm 3.6\%$

#### DATA COMPUTATIONS

The load factor,  $n_z$ , for each normal acceleration peak was measured directly from the oscillogram trace. However, to present load factors for positive and negative peaks conveniently, an incremental normal load factor,  $\Delta n_z$ , was derived from each  $n_z$  value by using the relationship

$$\Delta n_z = n_z - 1.0$$

The following equation (see Reference 6) was used to compute density altitude, since this parameter is normally used in describing helicopter performance:

$$h_d = 145,300 \left[ 1 - \left( \frac{518.4 P_a}{29.92 (OAT + 460)} \right)^{0.235} \right]$$

Since the instrument installation correction to derive the calibrated airspeed was judged to be negligible, only indicated airspeeds were considered. Rotor rpm and outside air temperature were computed by applying linear calibrations to the trace measurements. With the displacements of the stick position traces representing the deflections of the longitudinal cyclic stick from the full-forward position and the deflections of the collective stick from the full-down position, the respective stick positions were computed from the trace measurements in units of percent of full deflection. By an approximate differentiation of the altitude trace, the rate of climb was computed continuously during each segment. At the same time that the rate of climb was computed, the "longitudinal acceleration," or rate of change of airspeed, was derived by an approximate differentiation of the airspeed trace.

## DATA PRESENTATION

As discussed in the Introduction, 408 of the 436 valid data hours were separated chronologically into two data sets of about 200 hours each to test the validity of 200 hours as an adequate data sample. Accordingly, the first 202 hours recorded by April 1969 made up the first set and was identified as Sample I, and the remaining 206 hours collected through the rest of the recording period constituted the second set and was termed Sample II.

The data presented in this report consist of two types of figures and two types of tables. The two graphic types are histograms of the percentages of time within various parameter ranges and plots of the time in hours to reach or exceed given levels of the incremental vertical load factor,  $\Delta n_z$ . For convenience, these plots have been called "exceedance curves." The two tabular types are flight time distributed among the coincident ranges of two or more parameters, and the vertical acceleration peak frequencies distributed among the ranges of the vertical load factor,  $n_z$ , and the coincident ranges of other variables.

### DISCUSSION OF FIGURES

All graphs depicting the results from the two data samples are shown in Figures 3 through 28. The graphic representations for Samples I and II are presented consecutively.

For the direct comparison of the flight time spent in the mission segments, Figures 3 and 4 show histograms for the percentage of total flight time spent in each mission segment, and Figures 5 and 6 show histograms for the percentage of flight time in each gross weight range spent in each mission segment. The comparison of the two data samples in Figures 3 and 4 indicates that most of the larger percentage for the maneuver segment in Sample I is offset by the larger percentage for the steady-state segment in Sample II. This difference is attributed to the Sample II flights being generally longer than the Sample I flights, since the Sample I flights averaged 1.12 hours and the Sample II flights 1.42 hours. In general, however, the two data samples compare closely.

The favorable comparison of the two sets of percentages is further evidenced by the contrast of these percentages with those previously presented as a guide for the expected distribution of the AH-1G flight time among the four Vietnam mission segments. In the given order of the mission segments, data extracted from the usage projections of the Bell Helicopter Company give the following distribution: ascent, 6.5%; maneuver, 27.4%; descent, 2.0%; and steady state, 63.1%. The largest discrepancies

in the comparison of these percentages with those in the data samples are in the maneuver and the steady-state segments. These differences are ascribed to the fact that the anticipated sustained cruise to and from the target area was higher than that actually measured in the data of most of the flights. The actual combat data revealed that the AH-1G's, while en-route to and from the target areas, frequently left cruise altitudes with abrupt ascents and descents for apparent searches of enemy activity. Some of these departures were weapon passes; others were sufficiently pronounced in parameter changes to be also classified in the maneuver segment.

Figures 7 through 20 present histograms of the percentage of time spent in the parameter ranges during each mission segment. Figures 7 and 8 for gross weight show that almost all the time in each data sample was spent between 8,000 and 10,000 pounds. The comparison of the two data samples shows that the Sample I data have more time in the 9,000- to 10,000-pound range than the Sample II data. This difference is attributed to the shorter flights of Sample I. Since most of the flights took off at maximum weight, the shorter flights would, of course, result in a greater percentage of time at the higher weights.

Two armament configurations, known as the light Hog and the heavy Scout, prevailed in most flights. The takeoff weight of the light Hog with two XM-159C's and two XM-157's varied from 9187 to 9410 pounds, and that of the heavy Scout with two XM-18's and two XM-159's ranged from 9299 to 9522 pounds. These weights varied because of the various mission configuration and fuel combinations. For example, some flights took off with 1400 pounds of fuel instead of the normal 1200 pounds.

The rotor rpm distribution in Figures 9 and 10 show that more than 95 percent of the time in both data samples was flown between 310 and 325 rpm with the normal steady value being between 315 and 318. A very small amount of time was recorded in the 340- to 355-rpm range during the maneuver segment. All such recordings occurred during weapon pass descents. The highest value of 351 rpm was recorded during a descent which appeared to approach an autorotation. Rotor rpm limits are 294 to 324 rpm for continuous operation and 339 rpm maximum for autorotation.

Figures 11 and 12 indicate that most of the AH-1G flight time was spent within the 2000- to 5000-foot density altitude range for all four mission segments. These figures also indicate a small amount of time above 10,000 feet and none above 15,000 feet. The higher percentage of time above 2000 feet in the Sample II data is attributed to two factors: (1) the longer Sample II flights with a greater part of the flight at the higher

cruise altitudes, and (2) the greater number of Sample II flights during the summer months when the temperatures averaged slightly higher than those during the rest of the year, thereby accounting for the higher density altitude.

In the breakdown of the mission segment time by the percentage in the ranges of outside air temperature, Figures 13 and 14 show that the range of 70° to 80°F dominated in the Sample I data but that the range of 80° to 90°F generally prevailed in the Sample II data. As discussed in the previous paragraph, the higher temperatures in the Sample II data contributed to the higher density altitudes in these data.

Figures 15 and 16 show that most of the time in climbs and descents was spent in the range of  $\pm$  300-foot-per-minute altitude changes. Of particular note is the close correlation between the percentages in the corresponding mission segments of the two data samples. Such correlation indicates that pilot operating procedures remained uniform throughout the recording period.

Figures 17 and 18 show the percentage of flight time spent in each engine torque range of each mission segment. Most of the time was spent at torques between 20 and 50 psi, a small amount of time above 60 psi, and none above 70 psi. The greater percentage of time of the Sample II data in the higher torque ranges during the steady-state segment is attributed to the higher density altitudes in these data. The maximum continuous torque limit is 50 psi.

For the airspeed study, Figures 19 and 20 show both data samples with nearly two-thirds of the flight time in the 80- to 120-knot range, the normal operational range for the AH-1G. Only the descent and maneuver segments in both data samples had any time recorded at airspeeds above 150 knots. The maximum airspeed attained in the Sample I data was 185 knots and that in the Sample II data was 183 knots. The first occurred at an altitude of 5300 feet and a gross weight of 7546 pounds as the aircraft was pulling out of a descent at 5000 feet per minute; the second occurred at an altitude of 3447 feet and a gross weight of 8763 pounds as the aircraft was performing a weapons pass. In general, the airspeed during weapons passes ranged between 115 and 130 knots. The maximum allowable airspeed is 190 knots.

Figures 21 through 24 present exceedance curves of the time to reach or exceed given incremental normal load factor levels. For both positive and negative peaks, Figures 21 and 22 show the exceedance curves for each mission segment, and Figures 23 and 24 do the same for each gross

weight range. The curves for the respective mission segments and weight ranges do not deviate from expected patterns, and the comparison of the corresponding curves in the two data samples indicates a reasonable agreement. The composite curves for the two data samples in Figures 21 and 22 are in close agreement for the positive peaks up to  $0.8 \Delta n_z$ ; thereafter, the Sample I curve evidences higher frequencies to indicate that the load factor spectrum for the Sample I data is more severe at the higher  $\Delta n_z$  levels.

For the practical illustration of the relationship between maneuver load factor peaks,  $n_z$ , and tip speed ratio,  $\mu$ , Figures 25 and 26 represent the frequency of such peaks in coincident normal load factor and tip speed ratio ranges by first giving a range-symbol plot and then an actual number tabulation of the frequencies. That both data samples have the greatest concentration centered on the combined ranges of 1.2 to 1.3 normal load factor and 0.15 to 0.20 tip speed ratio is stressed by the solid symbols in the range-symbol plot. Again, the two data samples are in close agreement.

Figures 27 and 28 present, for both positive and negative peaks, exceedance curves of the time to reach or exceed given incremental normal load factor levels. Although the comparison of the two data samples indicates that the gust loads in the Sample II data are considerably more severe than those in the Sample I data, no definitive conclusions should be drawn because the extensive maneuvering of the helicopters made it difficult to distinguish the maneuver-induced peaks from the gust-induced ones in the oscillogram recordings.

#### DISCUSSION OF TABLES

All final computer printouts resulting from the processing of the 408 hours of valid data are presented in Tables IV through XXXVIII for the Sample I data, and Tables XXXIX through LXXIII for the Sample II data. All times in these tables were rounded off to the nearest tenth of a minute. Therefore, the "TOTAL" time and the individual times in each table are accurate to within 0.05 minute. However, since the individual times comprising the respective totals were summed before the totals were rounded off, the sum of individual times may differ from the corresponding printed total time by some tenths of a minute. Any time between 0 and up to but not including 0.05 minute was printed as "0.0", and no time measured was printed as "0.". Tables having neither points nor time were not printed.

Table headings are arranged so that the first-mentioned variable refers to the horizontal ranges at the top of the table and the second-mentioned variable refers to the vertical ranges at the left of the table. Where a third or a fourth variable is given, it is followed by its range in the heading. As an example, the heading "MINUTES FOR ALTITUDE VS AIR-SPEED BY WEIGHT 6000 BY MISSION SEG. ASCENT" indicates the time spent in coincident ranges of altitude and airspeed at a weight between 6000 and 7000 pounds during the ascent mission segment. All printed range values are the lower limits.

Tables IV through VIII for Sample I and Tables XXXIX through XLIII for Sample II give the flight time recorded in the coincident ranges of the various variables. In the tables containing engine torque data, the total time is less than that reported for the entire program. This discrepancy was due to the difficulty of recording valid engine torque data. Rather than expending more time and funds to meet the requirements of 400 hours of valid engine torque data, Technology Incorporated, with the approval of USAAVLABS, simply processed the available valid data. Still, the final data came close to the requirement since the engine torque data in Sample I represents 166 hours and that in Sample II, 170 hours.

To analyze the stick position variations, Tables IX through XXII for Sample I and Tables XLIV through LVII for Sample II present the frequencies of stick position peaks in the coincident ranges of each of the two stick positions and other variables.

For the review of the normal accelerations encountered, Tables XXIII through XXVI for Sample I and Tables LVIII through LXI for Sample II present the frequencies of both the maneuver and the gust normal acceleration peaks in the coincident ranges of incremental normal load factor and other variables.

Tables XXVIII through XXXII for Sample I and Tables LXII through LXVII for Sample II present the frequencies of the longitudinal and lateral acceleration peaks in the coincident ranges of the corresponding load factor and other variables.

Finally, for the correlation of the accelerations along each of the three major axes, Tables XXIII through XXXVIII for the Sample I data and Tables LXVIII through LXXIII for the Sample II data present the peak frequencies of each type of acceleration in the coincident ranges of the given type of acceleration and of each of the other two types.

### SUMMARY AND CONCLUSIONS

The AH-1G program produced twofold results: (1) a set of comprehensive loads and operational data defining the AH-1G performance in the combat environment of Vietnam, and (2) evidence that 200 hours of recorded data serves as a valid data sample. The resultant data may be used to determine the loading spectrum for cyclic load tests on helicopter structures as well as to conduct a parametric fatigue analysis and, thereby, project the safe life of each helicopter. In the comparison of the histograms and exceedance curves for the first 202 hours of data (Sample I) and the second 206 hours (Sample II), not only did the two data samples agree closely, but all discrepancies were reasonably explained.

13. ABSTRACT From a structural flight loads program on three AH-1G helicopters, 408.2 hours of valid multichannel flight data were recorded as the helicopters operated from bases in Southeast Asia. Data were processed and analyzed according to four distinct flight phases, termed mission segments: (1) takeoff and ascent; (2) maneuver; (3) descent, flare, and landing; and (4) steady state. Data are presented in the form of time and occurrence tables, histograms, and exceedance curves. These data indicate the time spent in the mission segments and parameter ranges; the number of peak param- eter values occurring in the ranges of the given parameter, during each of the mis- sion segments, and in the ranges of one or more related parameters; and the time to reach or exceed given maneuver and gust normal load factors. The data are pre- sented in two samples of 201.7 hours and 206.5 hours. These samples, identified as Sample I and Sample II respectively, were obtained consecutively. Sample I was recorded between August 1968 and April 1969, and Sample II was recorded between April 1969 and November 1969. This separate presentation is made to permit an evaluation of the validity of the 200-hour sample as an adequate data base. The dif- ferences between the two samples were minor, and the two samples were observed to be similar in their distributions of flight data.
